Recently, the interest in the transport properties of the perfluorocarbons has grown noticeably. The reason for this is not only the wide application of these gases in semiconductor and CVD manufacturing, but also the fact that they are accumulating in the atmosphere. The Global Warming Potential of  $C_2F_6$  is almost as high as that of  $CO_2$ , and this is why it has been included in the Kyoto protocol as a greenhouse gas.

Our aim is to determine the potential parameters (PP) of the (n-6) Lennard Jones temperature-dependent potential (LJTDP) for  $C_2F_6$  following our procedure used earlier for a number of different gases, amongst them  $CF_4$  [1] and  $C_nH_{2n+2}$ ,  $n < 6$  [2]. The PP are obtained by fitting the LJTDP to a set of 70 experimental data points determined in the temperature range between 175 and 1000 K. In particular, there are 40 points for viscosity  $\eta$  [3-6], 19 for the second pVT-virial coefficient B [7,8] and 11 for the second acoustic virial coefficient  $\beta$  [9].

For the PP, our present results are: potential well depth  $\varepsilon/k = 438.7(7)K$ , equilibrium distance  $r_m = 5.144(7)\text{Å}$ , repulsive parameter  $n = 75.0(4)$ , and enlargement of the first vibrationally excited level  $\delta = 0.023(2)\text{Å}$ . The experimental results are reproduced with a mean deviation of 1.3 from experimental errors. A comparison with the recommended data of NIST demonstrates an acceptable agreement.
